## **CROSS-REFERENCE TO RELATED PATENT APPLICATIONS**

This application claims priority to U.S. Provisional Application Ser. No. 60/269,847, filed 02/21/2001.

## **FIELD OF THE INVENTION**

5           The present invention provides compounds that are active at metabotropic glutamate receptors, particularly compounds that are active as antagonists at metabotropic glutamate receptors, more particularly at the mGluR5 glutamate receptor.

## **BACKGROUND OF THE INVENTION**

10           Recent advances in the elucidation of the neurophysiological roles of metabotropic glutamate receptors have established these receptors as promising drug targets in the therapy of acute and chronic neurological and psychiatric disorders and diseases. However, the major challenge to the realization of this promise has been the development of metabotropic glutamate receptor subtype-  
15           selective compounds.

          Glutamate is the major excitatory neurotransmitter in the mammalian central nervous system (CNS). Glutamate produces its effects on central neurons by binding to and thereby activating cell surface receptors. These receptors have been divided into two major classes, the ionotropic and metabotropic glutamate  
20           receptors, based on the structural features of the receptor proteins, the means by which the receptors transduce signals into the cell, and pharmacological profiles.

          The metabotropic glutamate receptors (mGluRs) are G protein-coupled receptors that activate a variety of intracellular second messenger systems following the binding of glutamate. Activation of mGluRs in intact mammalian  
25           neurons elicits one or more of the following responses: activation of phospholipase C; increases in phosphoinositide (PI) hydrolysis; intracellular calcium release; activation of phospholipase D; activation or inhibition of adenylyl cyclase; increases

or decreases in the formation of cyclic adenosine monophosphate (cAMP); activation of guanylyl cyclase; increases in the formation of cyclic guanosine monophosphate (cGMP); activation of phospholipase A<sub>2</sub>; increases in arachidonic acid release; and increases or decreases in the activity of voltage- and ligand-gated ion channels. Schoepp *et al.*, *Trends Pharmacol. Sci.* 14:13 (1993); Schoepp, *Neurochem. Int.* 24:439 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995).

Eight distinct mGluR subtypes, termed mGluR1 through mGluR8, have been identified by molecular cloning. *See, for example*, Nakanishi, *Neuron* 13:1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995). Further receptor diversity occurs via expression of alternatively spliced forms of certain mGluR subtypes. Pin *et al.*, *PNAS* 89:10331 (1992); Minakami *et al.*, *BBRC* 199:1136 (1994); Joly *et al.*, *J. Neurosci.* 15:3970 (1995).

Metabotropic glutamate receptor subtypes may be subdivided into three groups, Group I, Group II, and Group III mGluRs, based on amino acid sequence homology, the second messenger systems utilized by the receptors, and by their pharmacological characteristics. Nakanishi, *Neuron* 13:1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995).

Group I mGluRs comprise mGluR1, mGluR5, and their alternatively spliced variants. The binding of agonists to these receptors results in the activation of phospholipase C and the subsequent mobilization of intracellular calcium. Electrophysiological measurements have been used to demonstrate these effects, for example, in *Xenopus* oocytes that express recombinant mGluR1 receptors. *See, for example*, Masu *et al.*, *Nature* 349:760 (1991); Pin *et al.*, *PNAS* 89:10331 (1992). Similar results have been achieved with oocytes expressing recombinant mGluR5 receptors. Abe *et al.*, *J. Biol. Chem.* 267:13361 (1992); Minakami *et al.*, *BBRC* 199:1136 (1994); Joly *et al.*, *J. Neurosci.* 15:3970 (1995). Alternatively, agonist activation of recombinant mGluR1 receptors expressed in Chinese hamster ovary (CHO) cells stimulates PI hydrolysis, cAMP formation, and arachidonic acid release as measured by standard biochemical assays. Aramori *et al.*, *Neuron* 8:757 (1992).

By comparison, the activation of mGluR5 receptors, expressed in CHO cells, stimulates PI hydrolysis and subsequent intracellular calcium transients, but no stimulation of cAMP formation or arachidonic acid release is observed. Abe *et al.*,

*J. Biol. Chem.* 267:13361 (1992). However, activation of mGluR5 receptors expressed in LLC-PK1 cells results in PI hydrolysis and increased cAMP formation. Joly *et al.*, *J. Neurosci.* 15:3970 (1995). The agonist potency profile for Group I mGluRs is quisqualate > glutamate = ibotenate > (2*S*,1'*S*,2'*S*)-2-

5 carboxycyclopropyl)glycine (L-CCG-I) > (1*S*,3*R*)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD). Quisqualate is relatively selective for Group I receptors, as compared to Group II and Group III mGluRs, but it also is a potent activator of ionotropic AMPA receptors. Pin *et al.*, *Neuropharmacology* 34:1, Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995).

10 The lack of subtype-specific mGluR agonists and antagonists has impeded elucidation of the physiological roles of particular mGluRs, and the mGluR-associated pathophysiological processes that affect the CNS have yet to be defined. However, work with the available non-specific agonists and antagonists has yielded some general insights about the Group I mGluRs as compared to the  
15 Group II and Group III mGluRs.

Attempts at elucidating the physiological roles of Group I mGluRs suggest that activation of these receptors elicits neuronal excitation. Various studies have demonstrated that ACPD can produce postsynaptic excitation upon application to neurons in the hippocampus, cerebral cortex, cerebellum, and thalamus, as well as  
20 other brain regions. Evidence indicates that this excitation is due to direct activation of postsynaptic mGluRs, but it also has been suggested that activation of presynaptic mGluRs occurs, resulting in increased neurotransmitter release. Baskys, *Trends Pharmacol. Sci.* 15:92 (1992); Schoepp, *Neurochem. Int.* 24:439 (1994); Pin *et al.*, *Neuropharmacology* 34:1(1995).

25 Pharmacological experiments implicate Group I mGluRs as the mediators of this excitatory mechanism. The effects of ACPD can be reproduced by low concentrations of quisqualate in the presence of ionotropicGluR antagonists. Hu *et al.*, *Brain Res.* 568:339 (1991); Greene *et al.*, *Eur. J. Pharmacol.* 226:279 (1992). Two phenylglycine compounds known to activate mGluR1, namely (*S*)-3-hydroxyphenylglycine ((*S*)-3HPG) and (*S*)-3,5-dihydroxyphenylglycine ((*S*)-DHPG),  
30 also produce excitation. Watkins *et al.*, *Trends Pharmacol. Sci.* 15:33 (1994). In addition, the excitation can be blocked by (*S*)-4-carboxyphenylglycine ((*S*)-4CPG), (*S*)-4-carboxy-3-hydroxyphenylglycine ((*S*)-4C3HPG), and (+)-alpha-methyl-4-

carboxyphenylglycine ((+)-MCPG), compounds known to be mGluR1 antagonists. Eaton *et al.*, *Eur. J. Pharmacol.* 244:195 (1993); Watkins *et al.*, *Trends Pharmacol. Sci.* 15:333 (1994).

Metabotropic glutamate receptors have been implicated in a number of normal processes in the mammalian CNS. Activation of mGluRs has been shown to be required for induction of hippocampal long-term potentiation and cerebellar long-term depression. Bashir *et al.*, *Nature* 363:347 (1993); Bortolotto *et al.*, *Nature* 368:740 (1994); Aiba *et al.*, *Cell* 79:365 (1994); Aiba *et al.*, *Cell* 79:377 (1994). A role for mGluR activation in nociception and analgesia also has been demonstrated. Meller *et al.*, *Neuroreport* 4: 879 (1993). In addition, mGluR activation has been suggested to play a modulatory role in a variety of other normal processes including synaptic transmission, neuronal development, apoptotic neuronal death, synaptic plasticity, spatial learning, olfactory memory, central control of cardiac activity, waking, motor control, and control of the vestibulo-ocular reflex. Generally, see Nakanishi, *Neuron* 13: 1031 (1994); Pin *et al.*, *Neuropharmacology* 34:1; Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995).

Metabotropic glutamate receptors also have been suggested to play roles in a variety of pathophysiological processes and disease states affecting the CNS. These include stroke, head trauma, anoxic and ischemic injuries, hypoglycemia, epilepsy, and neurodegenerative diseases such as Alzheimer's disease. Schoepp *et al.*, *Trends Pharmacol. Sci.* 14:13 (1993); Cunningham *et al.*, *Life Sci.* 54:135 (1994); Hollman *et al.*, *Ann. Rev. Neurosci.* 17:31 (1994); Pin *et al.*, *Neuropharmacology* 34:1 (1995); Knopfel *et al.*, *J. Med. Chem.* 38:1417 (1995). Much of the pathology in these conditions is thought to be due to excessive glutamate-induced excitation of CNS neurons. Because Group I mGluRs appear to increase glutamate-mediated neuronal excitation via postsynaptic mechanisms and enhanced presynaptic glutamate release, their activation probably contributes to the pathology. Accordingly, selective antagonists of Group I mGluR receptors could be therapeutically beneficial, specifically as neuroprotective agents, analgesics, or anticonvulsants.

Preliminary studies assessing therapeutic potentials with the available mGluR agonists and antagonists have yielded seemingly contradictory results. For example, it has been reported that application of ACPD onto hippocampal neurons

leads to seizures and neuronal damage (Sacaan *et al.*, *Neurosci. Lett.* 139:77 (1992); Lipparti *et al.*, *Life Sci.* 52:85 (1993). Other studies indicate, however, that ACPD inhibits epileptiform activity, and also can exhibit neuroprotective properties. Taschenberger *et al.*, *Neuroreport* 3:629 (1992); Sheardown, *Neuroreport* 3:916 (1992); Koh *et al.*, *Proc. Natl. Acad. Sci. USA* 88:9431 (1991); Chiamulera *et al.*, *Eur. J. Pharmacol.* 216:335 (1992); Siliprandi *et al.*, *Eur. J. Pharmacol.* 219:173 (1992); Pizzi *et al.*, *J. Neurochem.* 61:683 (1993).

It is likely that these conflicting results are due to the lack of selectivity of ACPD, which causes activation of several different mGluR subtypes. In the studies finding neuronal damage it appears that Group I mGluRs were activated, thereby enhancing undesirable excitatory neurotransmission. In the studies showing neuroprotective effects it appears that activation of Group II and/or Group III mGluRs occurred, inhibiting presynaptic glutamate release, and diminishing excitatory neurotransmission.

This interpretation is consistent with the observation that (*S*)-4C3HPG, a Group I mGluR antagonist and Group II mGluR agonist, protects against audiogenic seizures in DBA/2 mice, while the Group II mGluR selective agonists DCG-IV and L-CCG-I protect neurons from NMDA- and KA-induced toxicity. Thomsen *et al.*, *J. Neurochem.* 62:2492 (1994); Bruno *et al.*, *Eur. J. Pharmacol.* 256:109 (1994); Pizzi *et al.*, *J. Neurochem.* 61:683 (1993).

Based on the foregoing, it is clear that a lack of potency and selectivity limits the value of the mGluR agonists and antagonists now available. In addition, most currently available compounds are amino acids or amino-acid derivatives which have limited bioavailabilities, thereby hampering *in vivo* studies to assess mGluR physiology, pharmacology, and therapeutic potential. On the other hand, compounds that selectively inhibit activation of metabotropic glutamate receptor Group I subtypes are indicated for treatment of neurological disorders and diseases such as senile dementia, Parkinson's disease, Alzheimer's disease, Huntington's Chorea, pain, epilepsy, head trauma, anoxic and ischemic injuries, and psychiatric disorders such as anxiety, schizophrenia and depression.

Accordingly, a need exists for potent mGluR agonists and antagonists that display a high selectivity for a mGluR subtype, particularly a Group I receptor subtype.

## DETAILED DESCRIPTION OF THE INVENTION

10 The present invention provides compounds that are potent and selective antagonists of mGluR5. The compounds contemplated by the invention can be represented by the general formula:

15 where  $\text{Ar}^1$  is an optionally substituted heterocyclic moiety and  $\text{Ar}^2$  is an optionally substituted carbocyclic moiety. The G moiety is a group that not only covalently binds to the  $\text{Ar}^1$  and  $\text{Ar}^2$  moieties and facilitates adoption of the correct spatial orientation of  $\text{Ar}^1$  and  $\text{Ar}^2$ , but may itself interact with the protein to allow receptor binding.

The  $\text{Ar}^1$  moiety is generally defined as a heterocyclic moiety, and the  $\text{Ar}^2$  moiety is generally defined as a carbocyclic moiety.  $\text{Ar}^1$  and  $\text{Ar}^2$  can be monocyclic or fused bicyclic groups.  $\text{Ar}^2$  is preferably defined as an aryl or alkaryl moiety.  $\text{Ar}^1$  is preferably defined as a heterocyclic, heteroaryl or heteroarylalkyl moiety. The ring systems encompassed by  $\text{Ar}^1$  can contain up to four heteroatoms, independently selected from the group consisting of N, S, and O. When  $\text{Ar}^1$  is a heteroaryl ring or ring system, it preferably contains one or two heteroatoms. At 25 least one of the heteroatoms preferably is nitrogen (N). #### Testing of compounds for mGluR Group I antagonist activity

The pharmacological properties of the compounds of the invention can be analyzed using standard assays for functional activity. Examples of glutamate  
25 receptor assays are well known in the art, for example, see Aramori *et al.*, *Neuron* 8:757 (1992); Tanabe *et al.*, *Neuron* 8:169 (1992); Miller *et al.*, *J. Neuroscience* 15: 6103 (1995); Balazs, *et al.*, *J. Neurochemistry* 69:151 (1997). The methodology described in those publications is incorporated herein by reference.

30 Conveniently, the compounds of the invention can be studied by means of an assay that measures the mobilization of intracellular calcium, [Ca<sup>2+</sup>]<sub>i</sub> in cells expressing mGluR5 that can bind the compounds. A well-known cell line which is suitable for this purpose is described in Miller *et al.*, *J. Neuroscience* 15: 6103

(1995), the contents of which are hereby incorporated by reference. It has been shown that exposure to rat astrocytes to the growth factors, basic fibroblast growth factor, EGF, or transforming growth factor- $\alpha$  markedly increased the protein expression and functional activity of endogenous mGluR5 (Miller *et al.*, *J.*

5 *Neuroscience*, 15(9): 6103-6109, 1995).

In brief, primary astrocyte cultures were prepared from 3-5 day old Sprague-Dawley rat pups using a modification of Miller *et al.* were plated on poly-L lysine coated flasks in Dulbecco's modified Eagle's medium (DMEM) containing fetal calf serum (FCS). For cuvette analysis, cultures were up-regulated with growth factors  
10 in flasks for 3-5 days, then harvested and prepared for measurement of  $[Ca^{2+}]_i$  mobilization as previously described (Nemeth *et al.*, 1998).

For FLIPR analysis, cells were seeded on poly-D lysine coated clear bottom 96-well plates with black sides and analysis of  $[Ca^{2+}]_i$  mobilization was performed 3 days following the growth factor up-regulation.

15 FLIPR experiments were done using a laser setting of 0.800 W and a 0.4 second CCD camera shutter speed. Each FLIPR experiment was initiated with 180  $\mu$ L of buffer present in each well of the cell plate. After each addition of compound, the fluorescence signal was sampled 50 times at 1 second intervals followed by 3 samples at 5 second intervals. Responses were measured as the peak height of  
20 the response within the sample period.

EC<sub>50</sub> and IC<sub>50</sub> determinations were made from data obtained from 8 point concentration response curves (CRC) performed in duplicate. Agonist CRC were generated by scaling all responses to the maximal response observed for the plate. Antagonist block of the agonist challenge was normalized to the average response  
25 of the agonist challenge in 14 control wells on the same plate. A detailed protocol for testing the compounds of the invention is provided below at Example 6.

Preparation of pharmaceutical compositions containing mGluR antagonists, and  
their use in treating neurological disorders

The compounds of the present invention may be useful for treating  
30 neurological disorders or diseases. While these compounds typically will be used in therapy for human patients, they also can be used in veterinary medicine, to treat similar or identical diseases.

In therapeutic and/or diagnostic applications, the compounds of the invention can be formulated for a variety of modes of administration, including systemic and topical or localized administration. Techniques and formulations generally may be found in REMINGTON'S PHARMACEUTICAL SCIENCES (18th ed.), Mack Publishing Co.

(1990).

The compounds according to the invention are effective over a wide dosage range. For example, in the treatment of adult humans, dosages from about 0.01 to about 1000 mg, preferably from about 0.5 to about 100 mg, per day may be used. A most preferable dosage is about 2 mg to about 70 mg per day. The exact dosage will depend upon the route of administration, the form in which the compound is administered, the subject to be treated, the body weight of the subject to be treated, and the preference and experience of the attending physician.

Pharmaceutically acceptable salts are generally well known to those of ordinary skill in the art, and may include, by way of example but not limitation, acetate, benzenesulfonate, besylate, benzoate, bicarbonate, bitartrate, bromide, calcium edetate, camsylate, carbonate, citrate, edetate, edisylate, estolate, esylate, fumarate, gluceptate, gluconate, glutamate, glycolylarsanilate, hexylresorcinate, hydrabamine, hydrobromide, hydrochloride, hydroxynaphthoate, iodide, isethionate, lactate, lactobionate, malate, maleate, mandelate, mesylate, mucate, napsylate, nitrate, pamoate (embonate), pantothenate, phosphate/disphosphate, polygalacturonate, salicylate, stearate, subacetate, succinate, sulfate, tannate, tartrate, or teoclate. Other pharmaceutically acceptable salts may be found, for example, in REMINGTON'S PHARMACEUTICAL SCIENCES (18th ed.), *supra*.

Preferred pharmaceutically acceptable salts include, for example, acetate, benzoate, bromide, carbonate, citrate, gluconate, hydrobromide, hydrochloride, maleate, mesylate, napsylate, pamoate (embonate), phosphate, salicylate, succinate, sulfate, or tartrate.

Depending on the specific conditions being treated, such agents may be formulated into liquid or solid dosage forms and administered systemically or locally. The agents may be delivered, for example, in a timed- or sustained-release form as is known to those skilled in the art. Techniques for formulation and administration may be found in REMINGTON'S PHARMACEUTICAL SCIENCES; (18th ed.),

*supra*. Suitable routes may include oral, buccal, sublingual, rectal, transdermal, vaginal, transmucosal, nasal or intestinal administration; parenteral delivery, including intramuscular, subcutaneous, intramedullary injections, as well as intrathecal, direct intraventricular, intravenous, intraperitoneal, intranasal, or  
5 intraocular injections, *inter alia*.

For injection, the agents of the invention may be formulated in aqueous solutions, preferably in physiologically compatible buffers such as Hank's solution, Ringer's solution, or physiological saline buffer. For such transmucosal administration, penetrants appropriate to the barrier to be permeated are used in  
10 the formulation. Such penetrants are generally known in the art.

Use of pharmaceutically acceptable carriers to formulate the compounds herein disclosed for the practice of the invention into dosages suitable for systemic administration is within the scope of the invention. With proper choice of carrier and suitable manufacturing practice, the compositions of the present invention, in  
15 particular, those formulated as solutions, may be administered parenterally, such as by intravenous injection. The compounds can be formulated readily using pharmaceutically acceptable carriers well known in the art into dosages suitable for oral administration. Such carriers enable the compounds of the invention to be formulated as tablets, pills, capsules, liquids, gels, syrups, slurries, suspensions and  
20 the like, for oral ingestion by a patient to be treated.

Pharmaceutical compositions suitable for use in the present invention include compositions wherein the active ingredients are contained in an effective amount to achieve its intended purpose. Determination of the effective amounts is well within the capability of those skilled in the art, especially in light of the detailed  
25 disclosure provided herein.

In addition to the active ingredients, these pharmaceutical compositions may contain suitable pharmaceutically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. The preparations formulated for oral  
30 administration may be in the form of tablets, dragees, capsules, or solutions.

Pharmaceutical preparations for oral use can be obtained by combining the active compounds with solid excipients, optionally grinding a resulting mixture, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to

obtain tablets or dragee cores. Suitable excipients are, in particular, fillers such as sugars, including lactose, sucrose, mannitol, or sorbitol; cellulose preparations, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, gum tragacanth, methyl cellulose, hydroxypropylmethyl-cellulose, sodium

carboxymethyl-cellulose (CMC), and/or polyvinylpyrrolidone (PVP: povidone). If desired, disintegrating agents may be added, such as the cross-linked polyvinylpyrrolidone, agar, or alginic acid or a salt thereof such as sodium alginate.

Dragee cores are provided with suitable coatings. For this purpose, concentrated sugar solutions may be used, which may optionally contain gum arabic, talc, polyvinylpyrrolidone, carbopol gel, polyethylene glycol (PEG), and/or titanium dioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dye-stuffs or pigments may be added to the tablets or dragee coatings for identification or to characterize different combinations of active compound doses.

Pharmaceutical preparations which can be used orally include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin, and a plasticizer, such as glycerol or sorbitol. The push-fit capsules can contain the active ingredients in admixture with filler such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid paraffin, or liquid polyethylene glycols (PEGs). In addition, stabilizers may be added.

The present invention will be understood more readily by reference to the following examples, which are provided by way of illustration and are not intended to be limiting of the present invention.

Tables 1, 2, and 3 summarize specific exemplified compounds of the present invention.

### Preparation of mGluR Group I antagonists

Many starting materials for preparing the compounds of the present invention are available from commercial sources, such as Aldrich Chemical Company (Milwaukee, WI). Moreover, compounds of the invention are readily prepared, from available precursors, using straightforward transformations which are well known in the art. The skilled artisan will recognize that mGluR Group I antagonists, according to the invention, can be prepared via methodology that is well known, using widely recognized techniques of organic chemistry. Suitable reactions are described in standard textbooks of organic chemistry. For example, see March, ADVANCED ORGANIC CHEMISTRY, 2d ed., McGraw Hill (1977).

More specifically, compounds of the invention generally can be prepared by formation of the G moiety between two precursor compounds containing suitable Ar<sup>1</sup> and Ar<sup>2</sup> moieties. When the linker contains a 1,2,4-oxadiazole, the heterocycle may be formed using well known techniques, such as reaction between an amidoxime and an acid chloride, or by the reaction of an amidoxime and an acylimidazole. An illustration of such a transformation is provided in Examples 4 and 5, below.

Amidoximes can be prepared using well known techniques by the reaction of an Ar<sup>1</sup> substituted nitrile with hydroxylamine. An illustration of such a transformation is provided below in Example 1.

In most cases, the precursor Ar<sup>2</sup> acid chlorides are readily available, or may be prepared using straightforward techniques of organic chemistry. For example, carboxylic acids may be converted into the corresponding acid chlorides by reaction with, for example, thionyl chloride or oxalyl chloride.

In the case where the linker contains a 1,3-oxazole, compounds were prepared using a procedure similar to that given by Kelly et al., J. Org. Chem. 61, 4623-4633 (1996). Thus, 3,5-disubstituted-1,3-oxazoles were prepared by mixing a haloketone with carboxamide in refluxing toluene for 3 days. The resulting

mixture was allowed to cool to room temperature, the solvent was removed and the residue was purified.

Scheme 2 illustrates another method for synthesizing compounds of the present invention. In particular, the method of scheme 2 is used to make the exemplified compound B144.

Other compounds of the present invention may readily be prepared by modifications to the reactions exemplified in the Schemes above, as will be appreciated by the skilled artisan.

## EXAMPLES

### General Experimental Methods

Capillary gas chromatographic and mass spectral data were obtained using a Hewlett-Packard (HP) 5890 Series II Gas Chromatograph coupled to an HP 5971 Series Mass Selective Detector [Ultra-2 Ultra Performance Capillary Column  
 15 (crosslinked 5% PhMe silicone); column length, 25 m; column i.d., 0.20 mm; helium flow rate, 60 mL/min; injector temp., 250 °C; temperature program, 20 °C/min from 125 to 325 °C for 10 min, then held constant at 325 °C for 6 min]. Thin-layer chromatography was performed using Analtech Uniplat 250-μm silica gel HF TLC plates. UV light sometimes in conjunction with ninhydrin and

Dragendorff's spray reagents (Sigma Chemical Co.) were used for detecting compounds on the TLC plates. Most reagents used in reactions were purchased from the Aldrich Chemical Co. (Milwaukee, WI), Sigma Chemical Co. (Saint Louis, MO), Fluka Chemical Corp. (Milwaukee, WI), Fisher Scientific (Pittsburgh, PA), TCI America (Portland, OR), or Lancaster Synthesis (Windham, NH).

### Example 1: Synthesis of Amidoxime Intermediates

Using the general procedure of Shine et al., *J. Heterocyclic Chem.* (1989) 26:125-128, hydroxylamine hydrochloride (7.65 g, 110 mmol) in ethanol (100 mL) was treated with a 10N solution of sodium hydroxide (11 mL, 110 mmol). A precipitate quickly formed and the reaction mixture was stirred at room temperature for 30 min. The inorganic precipitate was filtered and rinsed with ethanol (100 mL). The filtrate and ethanol washings were combined and treated with 2-cyanopyridine (10.4 g, 100 mmol). The reaction mixture was then heated at reflux for 20 hours. After cooling, the volatiles were removed *in vacuo*, to afford 13.3 g (97%) of pyrid-2-ylamidoxime.

#### 5-Methyl-pyrid-2-ylamidoxime

The reaction was allowed to proceed for 1 hour, after which a precipitate formed. Water (100 mL) and ethyl acetate (1500 mL) were combined with the reaction in a separatory funnel, and the organic layer was collected, washed with brine and dried over sodium sulphate. ### 3-Iodo-5-Trifluoromethylbenzoic acid

The title product was prepared according to the literature procedure (Fujiki, Kanji; Kashiwagi, Mitsuyoshi; Miyamoto, Hideyuki; Sonoda, Akinari; Ichikawa, Junji; et al *J. Fluorine Chem.* **1992**, *57*, 307-321) from 3,5-bis(trifluoromethyl)benzene (7.3 mL, 47 mmol) and iodine (11.95 g, 47 mmol) in 30% oleum (30 mL) at 55 degrees for 15h. Quenching with ice was followed by extraction of the crude product into ether, sequential washing of the aqueous layer with sodium sulfite (1M) and water. Sodium hydroxide (1N, ~150 mL) was added to the crude ether solution until pH basic, the layers were separated and the aqueous layer was then acidified using HCl (12N, ~10 mL, pH acidic). Extraction into ether followed by drying over magnesium sulfate yielded the crude acid (4.3 g, 29%). The material was insufficiently pure for use, so the product was esterified using acetyl chloride in methanol, purified using flash chromatography (silica gel, 20% dichloromethane in hexane) and hydrolyzed with sodium hydroxide in methanol yielding 2.95 g (69%) of pure 3-iodo-5-Trifluoromethylbenzoic acid.

#### **EXAMPLE 11: Assay of Group I receptor antagonist activity**

Primary astrocyte cultures were prepared from 3-5 day old Sprague-Dawley  
10 rat pups using a modification of Miller (Miller *et al*, *J. Neuroscience*, 15(9): 6103-6109, 1995). In brief, primary cultures were plated on poly-L lysine coated flasks in Dulbecco's modified Eagle's medium (DMEM) containing fetal calf serum (FCS). After 6 days, cell cultures were shaken over night at 280 rpm, then transferred to astrocyte-defined media (ADM) containing growth factors that up-regulate the  
15 expression of mGluR5 (Miller et al., 1995). For cuvette analysis, cultures were up-regulated with growth factors in flasks for 3-5 days, then harvested and prepared for measurement of [Ca<sup>2+</sup>]<sub>i</sub> mobilization as previously described (Nemeth et al., 1998).

For FLIPR analysis, cells were seeded on poly-D lysine coated clear bottom  
20 96-well plates with black sides and analysis of [Ca<sup>2+</sup>]<sub>i</sub> mobilization was performed 3 days following the growth factor up-regulation. Cell cultures in the 96-well plates were loaded with a 4  $\mu$ M solution of acetoxymethyl ester form of the fluorescent calcium indicator fluo-3 (Molecular Probes, Eugene, Oregon) in 0.01 % pluronic. All assays were performed in a buffer containing 127 mM NaCl, 5 mM  
25 KCl, 2 mM MgCl<sub>2</sub>, 0.7 mM NaH<sub>2</sub>PO<sub>4</sub>, 2 mM CaCl<sub>2</sub>, 0.422 mg/ml NaHCO<sub>3</sub>, 2.4 mg/ml HEPES, 1.8 mg/ml glucose and 1 mg/ml BSA Fraction IV (pH 7.4).

FLIPR experiments were done using a laser setting of 0.800 W and a 0.4 second CCD camera shutter speed. Each FLIPR experiment was initiated with 180  $\mu$ L of buffer present in each well of the cell plate. A 20  $\mu$ L addition from the  
30 antagonist plate was followed by a 50  $\mu$ L addition from the agonist plate. After

each addition the fluorescence signal was sampled 50 times at 1 second intervals followed by 3 samples at 5 second intervals. Responses were measured as the peak height of the response within the sample period.

5  $EC_{50}/IC_{50}$  determinations were made from data obtained from 8 point concentration response curves (CRC) performed in duplicate. Agonist CRC were generated by scaling all responses to the maximal response observed for the plate. Antagonist block of the agonist challenge was normalized to the average response of the agonist challenge in 14 control wells on the same plate. Compounds of the present invention antagonized mGluR5 as determined by their  $IC_{50}$  values which fell  
10 into the range of 11 – 9140 nM.

The invention thus has been disclosed broadly and illustrated in reference to representative embodiments described above. Those skilled in the art will recognize that various modifications can be made to the present invention without departing from the spirit and scope thereof.
